analysis of raw data from cameraphone CMOS sensor (F&al.SensJ2007)
1. Rudiments of Noise Modeling
Additive White Gaussian Noise (AWGN) model

\[ z(x) = y(x) + \sigma \xi(x) \quad x \in X \]

- \( y : X \rightarrow Y \subseteq \mathbb{R} \) unknown original image (deterministic)
- \( \sigma \xi(x) \) i.i.d. zero-mean random error
- \( z : X \rightarrow Z \subseteq \mathbb{R} \) observed noisy image (random)
- \( x \in X \subseteq Z \) coordinate in the image domain

- \( \sigma \in \mathbb{R}^+ \) standard deviation of \( \sigma \xi(x) \)
- \( \xi(x) \) normal random variable \( E \{ \xi(x) \} = 0 \) \( \text{var} \{ \xi(x) \} = 1 \)

\[
E \{ z(x) \} = y(x) \quad \text{expectation}
\]
\[
\text{std} \{ z(x) \} = \sigma \text{std} \{ \xi(x) \} = \sigma \quad \text{standard deviation}
\]

!! Often \( z, \xi \) are used to denote the random variables/processes (when dealing with the model) as well as their realizations (when dealing with the algorithm).
Additive White Gaussian Noise (AWGN) model

\[ z = y + \sigma \xi \]
Additive *White* Gaussian Noise (AWGN) model

white:

\[
\text{var } \{ \mathcal{F}(\sigma \xi) \} = \text{constant} \quad \text{(noise power spectrum is flat)}
\]

This nomenclature is perhaps misleading.

What we demand is \( \sigma \xi(x) \) to be *independent* and *identically distributed*.

identically distributed:

\[
\Pr[\sigma \xi(x_1) < c] = \Pr[\sigma \xi(x_2) < c] \quad \forall c \in \mathbb{R}
\]

independent:

\[
\Pr[\sigma \xi(x_1) < c] \Pr[\sigma \xi(x_2) < d] = \Pr[\{\sigma \xi(x_1) < c\} \cap \{\sigma \xi(x_2) < d\}] \quad \forall c, d \in \mathbb{R}
\]
Additive *White* Gaussian Noise (AWGN) model

independence implies whiteness:

\[
\mathcal{F}(\sigma \xi)(\omega) = \sum_{x \in X} e^{-2\pi i \omega x} \sigma \xi(x)
\]

\[
\text{var} \{ \mathcal{F}(\sigma \xi)(\omega) \} = \sum_{x \in X} |e^{-2\pi i \omega x}|^2 \text{ var} \{ \sigma \xi(x) \} =
\]

\[
= \sum_{x \in X} \text{ var} \{ \sigma \xi(x) \} \quad [ = \sigma^2 |X| \quad \text{ because identically distributed}]
\]

We can have Gaussian white noise that is not i.i.d.!!

How? It suffices to have independent but non identically distributed errors.
Various examples of Gaussian white noise

They are all three Gaussian and white, but only the i.i.d. one is what is typically assumed as AWGN.

:-(
Colored noise

Noise is *colored* when the noise power spectrum is markedly not flat.

The band with larger variance determines the “color”.

Typically modeled by kernel convolution operator against white noise:

\[
\mathcal{F} (v \ast \xi) = \mathcal{F} (v) \mathcal{F} (\xi) \\
\text{var} \{ \mathcal{F} (v \ast \xi) \} = |\mathcal{F} (v)|^2 \text{var} \{ \mathcal{F} (\xi) \} 
\]
Homoskedasticity vs. Heteroskedasticity

The noise $\eta$ is **homoskedastic** if different noise samples have same variance:

$$\text{var}\{\eta(x')\} = \text{var}\{\eta(x'')\} \quad \forall x', x'' \in X$$

otherwise it is **heteroskedastic** and different noise samples can have different variance:

$$\text{var}\{\eta(x')\} \neq \text{var}\{\eta(x'')\} \quad \text{for some } x', x'' \in X.$$
Standard-deviation map

Let $z(x) = y(x) + \eta(x), \ x \in X,$ with $\eta$ heteroskedastic noise.

Whenever the variance $\text{var}\{\eta\}$ is deterministic, it makes sense to break $\eta$ into two factors:

$$\eta = \text{std}\{\eta\} \xi$$

- $\text{std}\{\eta\} : X \to \mathbb{R}^+$ standard-deviation map (deterministic)
- $\xi : X \to \mathbb{R}$ homoskedastic noise (random)
- $\text{std}\{\xi\}(x) = 1 \ \forall x \in X$
Signal-dependent noise

The $\eta$ noise is **signal-dependent** when the distribution of $\eta(x)$ has some parameter that depends on $y(x)$:

$$\Pr[\eta(x) < c] = F(c, y(x)), \quad \forall x \in X \text{ and } \forall c \in \mathbb{R}$$

with $F$ functionally independent of $x$.

The most significant situation arises when the variance of $\eta$ depends on $y$, i.e. when the standard-deviation map becomes a function of $y$:

$$z(x) = y(x) + \sigma(y(x)) \xi(x), \quad x \in X,$$

where $\sigma : \mathbb{R} \to \mathbb{R}^+$ is the **standard-deviation function or curve** (deterministic), $\xi(x)$ is a random variable $E\{\xi(x)\} = 0$, $\text{var}\{\xi(x)\} = 1$.

$\xi$ is homoskedastic noise with unitary variance.

The distribution of $\xi(x)$ may depend on $y(x)$, but what most matters is its variance.
Multiplicative noise

Multiplicative noise is a special case of signal-dependent noise where the mean is the direct scaling parameter of the noise distribution.

\[ z(x) = y(x) \cdot \eta_{\text{mult}}(x), \quad x \in X, \]

\[ \eta_{\text{mult}} \text{ i.i.d. noise, } E\{\eta_{\text{mult}}(x)\} = 1, \quad \text{std}\{\eta_{\text{mult}}(x)\} = c. \]

Rewrite in additive signal-dependent form:

\[ z(x) = y(x) + y(x) (\eta_{\text{mult}}(x) - 1) = \]
\[ = y(x) + y(x) \xi'(x) = \]
\[ = y(x) + \sigma(y(x)) \xi(x), \]

where \( \sigma : \mathbb{R} \rightarrow \mathbb{R}^+, \quad \sigma : y \mapsto c|y| \)

and \( \xi(x) = \text{sign}\{y(x)\} c^{-1} \xi'(x) = \text{sign}\{y(x)\} c^{-1} (\eta_{\text{mult}}(x) - 1) \).

We have \( E\{\xi(x)\} = 0, \quad \text{var}\{\xi(x)\} = 1. \)
Poisson distributions

Poisson distributions are discrete integer-valued distributions with non-negative real-valued parameter (mean) $\theta \geq 0$

$$z \sim \mathcal{P}(\theta) \quad \Pr[z = \zeta | \theta] = e^{-\theta} \frac{\theta^\zeta}{\zeta!}, \quad \zeta \in \mathbb{N}.$$ 

$$\mu(\theta) = E\{z|\theta\} = \theta$$

$$\sigma^2(\theta) = \text{var}\{z|\theta\} = \theta = \mu(\theta)$$

mean and variance coincide and are equal to the parameter $\theta$

Matlab code: $z = \text{poissrnd}(\text{theta})$

signal-to-noise ratio (SNR): $\frac{\mu(\theta)}{\sigma(\theta)} = \sqrt{\theta} \to 0 \quad \frac{\mu(\theta)}{\sigma(\theta)} \to +\infty$
Poisson distributions

\[ \sigma(\theta) \]

\[ \mu(\theta) \]

\[ \mu(\theta) \approx \theta \]

Discrete Poisson \( P(\theta) \) (blue) and continuous normal approximation \( N(\theta, \theta) \) (red)
Normal approximation of Poisson

\[ z \sim \mathcal{P}(\theta) \] means the probability of \( z \) \( \Pr[z = \zeta|\theta] = e^{-\theta} \frac{\theta^\zeta}{\zeta!}, \zeta \in \mathbb{N} \)

\[ z \sim \mathcal{N}(\mu, \sigma^2) \] means the probability density of \( z \) is

\[ \varphi(\zeta|\mu, \sigma^2) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(\zeta - \mu)^2}{2\sigma^2}}, \zeta \in \mathbb{R}. \]

\[ \mathcal{P}(\theta) \xrightarrow{\theta \to +\infty} \mathcal{N}(\theta, \theta) \]

Matlab code: \( z = z + \text{sqrt(theta)}.*\text{randn(size(theta))} \)
Normal approximation of Poisson

“p.d.f.” (top) and c.d.f. (bottom) for $\mathcal{P}(\theta)$ and $\mathcal{N}(\theta, \theta)$, $\theta = 2, 10, 20, 40$. 

$\mathcal{P}(\mu)$ and $\mathcal{N}(\mu; \mu)$, $\mu = 2, 10, 20, 40$. 

Normal approximation of Poisson
Scaled Poisson distributions

Scaled Poisson distributions with scale parameter $\chi > 0$ and mean $\theta \geq 0$

$$z\chi \sim \mathcal{P}(\theta\chi)$$

$$\Pr\{z = \zeta|\theta\} = e^{-\theta\chi}(\theta\chi)^{\zeta\chi}/(\zeta\chi)!,$$  

$\zeta\chi \in \mathbb{N}$,  

$\theta \in [0, +\infty)$.

Discrete taking values that are nonnegative integer multiples of $\frac{1}{\chi}$.

$$\mu(\theta) = E\{z|\theta\} = \theta$$

$$\sigma^2(\theta) = \text{var}\{z|\theta\} = \frac{\theta}{\chi}$$

mean is equal to the parameter $\theta$ and coincides with the variance times $\chi$.

The scale parameter $\chi$ controls the relative strength of the noise: $\text{SNR}\frac{\mu(\theta)}{\sigma(\theta)} = \sqrt{\chi \theta}$.

Matlab code: $z = \text{poissrnd}(\text{chi}*\text{theta})/\text{chi}$

Normal approximation for large $\theta$: $z \sim \mathcal{N}(\theta, \theta/\chi)$

Matlab code: $z = z + \text{sqrt(}\text{theta}/\text{chi})\cdot\text{randn(size(theta))}$
Scaled Poisson distributions

\[ \chi = 0.1, \ \theta = 2 \quad \chi = 1, \ \theta = 2 \quad \chi = 10, \ \theta = 2 \]

\[ \chi = 0.1, \ \theta = 7 \quad \chi = 1, \ \theta = 7 \quad \chi = 10, \ \theta = 7 \]

small \( \chi \) is detrimental when \( \theta \) varies on a narrow range of values
Poissonian noise

Let $y: X \rightarrow Y \subseteq \mathbb{R}^+$ be the original image (deterministic, possibly unknown). Let $\chi > 0$ be the scaling factor. Then

$$z(x) \sim \mathcal{P}(\chi y(x)), \quad \forall x \in X.$$

$$E\{z(x)\} = \chi E\{y(x)\} = \chi y(x) \quad \Rightarrow \quad E\{z(x)\} = y(x),$$

$$\text{var}\{z(x)\} = \chi^2 \text{var}\{y(x)\} = \chi y(x) \quad \Rightarrow \quad \text{var}\{z(x)\} = \frac{y(x)}{\chi}.$$  

This can be rewritten in the usual form as

$$z(x) = y(x) + \sqrt{\frac{y(x)}{\chi}} \xi(x), \quad \forall x \in X,$$

where $E\{\xi(x)\} = 0$ and $\text{var}\{\xi(x)\} = 1$. The term $\sqrt{\frac{y(x)}{\chi}} \xi(x)$ is the so-called Poissonian noise.
Scaled Poisson observations

\[ \chi = 1000 \]
Scaled Poisson observations

\[ \chi = 300 \]
Scaled Poisson observations

\[ \chi = 100 \]
Scaled Poisson observations

\[ \chi = 50 \]
Scaled Poisson observations

\( x = 10 \)
Scaled Poisson observations

$\chi = 1$
A one-parameter family of distributions $\mathcal{D} = \{D\}$ is a collection of distributions, each of which is identified by the value of a univariate parameter $\theta \in \Theta \subseteq \mathbb{R}$.

Let $z \in Z \subseteq \mathbb{R}$ be a random variable distributed according to a one-parameter family of distributions $\mathcal{D} = \{D\}$.

For each individual $\theta \in \Theta$: $D_\theta$ is a distribution, $z|\theta \sim D_\theta$, $z|\theta \in Z_\theta \subseteq Z$

$\mu(\theta) = E\{z|\theta\}$  conditional expectation of $z$ expressed as function of $\theta$.
$\sigma(\theta) = \text{std}\{z|\theta\}$  conditional standard deviation of $z$ expressed as function of $\theta$.

**Poisson example:**

$\Theta = [0, +\infty) \subseteq \mathbb{R}$
$D_\theta$ is one Poisson distribution with parameter $\theta \in \Theta$
$Z_\theta = \{0, 1, 2, \ldots\} = \mathbb{N}$
$\mu(\theta) = \theta$
$\sigma(\theta) = \theta$
| Distribution                          | pdf $[z|\theta]$                                                                 | $\mu(\theta)$ | $\sigma(\theta)$ |
|--------------------------------------|----------------------------------------------------------------------------------|----------------|------------------|
| **Poisson**                          | $e^{-\mu} \frac{\mu^z}{z!}$, $\mu \in \mathbb{R}$, $\theta \in [0, +\infty]$ | 0              | $\sqrt{\theta}$ |
| **Scaled Poisson** (scale $\chi > 0$) | $e^{-\mu \chi} \frac{\mu^z \chi^z}{z!}$, $\mu, \chi \in \mathbb{R}$, $\theta \in [0, +\infty]$ | 0              | $\sqrt{\theta}$ |
| **Binomial** (n trials)              | $\binom{n}{z} \theta^z (1-\theta)^{n-z}$, $\theta \in [0, 1]$                   | n$\theta$      | $\sqrt{n\theta(1-\theta)}$ |
| **Scaled binomial** (n trials, scale $n$) | $\binom{n}{z} \theta^z (1-\theta)^{n-z}$, $\theta \in [0, 1]$                   | 0              | $\sqrt{n\theta(1-\theta)}$ |
| **Negative binomial** (exponent $k$) | $\frac{\Gamma(z+k)}{\Gamma(z)\Gamma(k)} \left( \frac{\theta}{1-\theta} \right)^k \left( \frac{1-\theta}{\theta} \right)^z$, $\theta \in (0, +\infty)$ | 0              | $\sqrt{\frac{\theta^k}{1-\theta} \frac{\theta^{z+k}}{1-\theta}}$ |
| **Scaled negative binomial** (exponent $k$, scale $\chi > 0$) | $\frac{\Gamma(z+k)}{\Gamma(z)\Gamma(k)} \left( \frac{\theta}{1-\theta} \right)^k \left( \frac{1-\theta}{\theta} \right)^z$, $\theta \in (0, +\infty)$ | 0              | $\sqrt{\frac{\theta^k}{1-\theta} \frac{\theta^{z+k}}{1-\theta}}$ |
| **Multiplicative normal** (scale $\chi > 0$) | $\frac{1}{\sqrt{2\pi \chi^2}} e^{-\frac{(z-\mu\chi)^2}{2\chi^2}}$ | 0              | $\frac{1}{\sqrt{\chi}}$ |
| **Doubly censored normal with standard-deviation $s(\theta)$** | $\Phi \left( \frac{\mu(\theta)}{s(\theta)} \right) \delta_{u}(\zeta) + \frac{1}{\mu(\theta)} \Phi \left( \frac{\mu(\theta)}{s(\theta)} \right) \chi_{[\mu,1]} + \left( 1 - \Phi \left( \frac{\mu(\theta)}{s(\theta)} \right) \right) \delta_{1-\zeta}$ | 0              | $\frac{1}{\sqrt{\chi}}$ |
Multiplicative Gaussian noise \( \text{pdf} [z|\theta] (\zeta) \) (\( \chi = 1 \))
Multiplicative Gaussian noise \( \text{pdf} [z | \theta](\zeta) \quad (\chi = 10) \)
Poisson-Gaussian noise

Each observed pixel intensity value \( z(x), x \in X \), is composed of a scaled Poisson and an additive Gaussian component:

\[
z(x) = \alpha p(x) + n(x),
\]

where \( p(x) \sim \mathcal{P}(y(x)) \), \( y(x) \) is the unknown noise-free pixel intensity, \( \alpha > 0 \) is a gain or scaling parameter, and \( n(\cdot) \sim \mathcal{N}(0, \sigma^2) \).

Poisson-Gaussian noise is defined as

\[
\eta(x) = z(x) - \alpha y(x).
\]

Signal-dependent standard deviation:

\[
\text{std} \{ z(x) | y(x) \} = \sqrt{\alpha^2 y(x) + \sigma^2}.
\]
Rician-distributed data

Let $z \sim \mathcal{R}(\nu, \sigma)$ be the realization of a random variable with Rician p.d.f. with parameters $\nu \geq 0$ and $\sigma > 0$,

$$p(z|\nu, \sigma) = \frac{z}{\sigma^2} e^{-\frac{z^2 + \nu^2}{2\sigma^2}} I_0\left(\frac{z\nu}{\sigma^2}\right), \quad z \geq 0,$$

where $I_n$ denotes the modified Bessel function of order $n$.

Equivalently, $z = \sqrt{(c_r \nu + \sigma \eta_r)^2 + (c_i \nu + \sigma \eta_i)^2}$, where $c_r$ and $c_i$ are arbitrary constants such that $0 \leq c_r, c_i \leq 1 = c_r^2 + c_i^2$, and $\eta_r, \eta_i \sim \mathcal{N}(0, 1)$.

Observation model for magnitude magnetic resonance (MR) images/volumes:

$z(x) \sim \mathcal{R}(\nu(x), \sigma), \quad x \in X \subset \mathbb{Z}^d, \quad d = 2, 3$ (pixel or voxel coordinates).

$\nu : X \to \mathbb{R}^+$ is the unknown original (noise-free) signal

$z : X \to \mathbb{R}^+$ is the raw magnitude MR data.
The one-parameter family of Rician p.d.f.’s $\mathcal{R}(\nu, 1)$ for $\nu \in [0, 5]$.

The parameter $\sigma$ is assumed as fixed. Thus, $z$ is treated as distributed according to a one-parameter family of Rician distributions, parametrized with respect to $\nu$: $\mathcal{R}(\cdot, \sigma)$.

Assuming $\sigma = 1$ is not a serious restriction: $z \sim \mathcal{R}(\nu, \sigma)$ iff $\lambda z \sim \mathcal{R}(\lambda \nu, \lambda \sigma)$ $\forall \lambda > 0$.

Thanks to this scaling we can carry out all analysis for $\sigma = 1$, and then apply it to other cases $\sigma > 0$ upon simple linear rescaling of data and parameters.

Given $f : \mathbb{R}^+ \rightarrow \mathbb{R}$, we have that

\[
\text{var} \{ f(z) \mid \nu, \sigma \} = \text{var} \{ f_\lambda(w) \mid \lambda \nu, \lambda \sigma \},
\]

where $z \sim \mathcal{R}(\nu, \sigma)$, $w = \lambda z \sim \mathcal{R}(\lambda \nu, \lambda \sigma)$ and $f_\lambda(w) = f(w/\lambda)$ $\forall w \in \mathbb{R}^+$. 
Mean and variance of Rician data

The mean and variance of $z \sim \mathcal{R}(\nu, \sigma)$ are, respectively,

$$
\mu = E\{z|\nu, \sigma\} = \sigma \sqrt{\frac{\pi}{2}} L\left(-\frac{\nu^2}{2\sigma^2}\right),
$$

$$
\sigma^2 = \text{var}\{z|\nu, \sigma\} = 2\sigma^2 + \nu^2 - \frac{\pi\sigma^2}{2} L^2\left(-\frac{\nu^2}{2\sigma^2}\right),
$$

where $L(x) = e^{x^2/2} \left[(1 - x) I_0\left(-\frac{x}{2}\right) - x I_1\left(-\frac{x}{2}\right)\right]$.

For large values of $\nu$ we have

$$
E\{z|\nu, \sigma\} \approx \nu + \frac{\sigma^2}{2\nu}, \quad \text{var}\{z|\nu, \sigma\} \approx \sigma^2 - \frac{\sigma^4}{2\nu^2}.
$$

Two crucial issues follow from (2) and (3):

(3) implies that the noise variance is not uniform over the data.

the expectation (2) differs essentially from the parameter of interest, namely $\nu$.

The former problem is addressed by the (forward) variance-stabilizing transformation
applied to the data before prior to filtering, whereas the latter is addressed by the
inverse transformation applied upon filtering, which is designed so to directly provide an
estimate of $\nu$ out of the filtered transformed data.
Mean of Rician data

\[ E \{ z | \nu, 1 \} - \nu \]
Standard-deviation of Rician data

\[ \text{std}\left\{z|\nu,1\right\} \]
Rayleigh pdf $\{z|\theta\}(\zeta)$
Doubly censored normal (clipping from below and above)

Underlying normal p.d.f. (uncensored) drawn in red
Doubly censored normal as a model for clipped noisy data

original

added AWGN and then clipped

(F&al.TIP2008, F.SigPro2009)
Raw data as clipped signal-dependent observations

\[ \tilde{z}(x) = \max \{0, \min \{z(x), 1\}\}, \quad x \in X \subset \mathbb{Z}^2, \]

\[ z(x) = y(x) + \sigma(y(x)) \xi(x) \]

\( y : X \rightarrow Y \subseteq \mathbb{R} \) unknown original image (deterministic)

\( \sigma(y(x)) \xi(x) \) zero-mean random error

\( \sigma : \mathbb{R} \rightarrow \mathbb{R}^+ \) standard-deviation function (deterministic)

\( \xi(x) \) random variable \( E \{\xi(x)\} = 0 \) \( \text{var} \{\xi(x)\} = 1 \)

\( y(x) = E \{z(x)\} \) expectation

\( \sigma(y(x)) = \text{std} \{z(x)\} \) standard deviation
Raw data as clipped signal-dependent observations

\[ z(x) = y(x) + \sigma(y(x)) \xi(x) \]

\[ \bar{z}(x) = \max \{0, \min \{z(x), 1\}\}, \quad x \in X \subset \mathbb{Z}^2; \]

\[ \bar{z}(x) = \bar{y}(x) + \bar{\sigma}(\bar{y}(x)) \bar{\xi}(x) \]

\[ \bar{y}(x) = E\{\bar{z}(x) | \bar{y}(x)\} \quad \text{expectation} \]

\[ \bar{\sigma} : [0, 1] \to \mathbb{R}^+ \quad \text{standard-deviation function (of expectation)} \]

\[ \bar{\sigma}(\bar{y}(x)) = \text{std}\{\bar{z}(x) | \bar{y}(x)\} \quad \text{standard deviation} \]
Modeling raw-data signal-dependence before clipping\textsuperscript{56}

The random error before clipping is composed of two mutually independent parts:

$$\sigma (y(x)) \xi (x) = \eta_p (y(x)) + \eta_g (x)$$

$\eta_p$  \textit{Poissonian} signal-dependent component (photonic)

$\eta_g$  \textit{Gaussian} signal-independent component (everything else)

$$(y(x) + \eta_p (y(x))) \chi  \sim \mathcal{P}(\chi y(x)), \quad \chi > 0$$

$\eta_g (x)  \sim \mathcal{N}(0, b), \quad b > 0$

$$\sigma^2(y(x)) = ay(x) + b, \quad a = \chi^{-1}$$

Variance is an \textit{affine} function of mean.

Higher-order models (e.g., quadratic functions) are also possible and allow to better capture nonlinearities in sensor response.
Heteroskedastic normal approximation

\[ \hat{z}(x) = \max \{0, \min \{z(x), 1\}\}, \quad x \in X \subset \mathbb{Z}^2, \]

\[ z(x) = y(x) + \sigma(y(x)) \xi(x) \]

\[ \sigma(y(x)) \xi(x) = \sqrt{a y(x) + b \xi(x)}, \quad \xi(x) \sim \mathcal{N}(0, 1) \]
(Generalized) Probability distributions

Before clipping: \[ p_z(\zeta|y) = \frac{1}{\sigma(y)} \phi \left( \frac{\zeta - y}{\sigma(y)} \right) \]

After clipping: \[ p_z(\zeta|y) = \frac{1}{\sigma(y)} \phi \left( \frac{\zeta - y}{\sigma(y)} \right) \chi_{[0,1]}(\zeta) + \Phi \left( \frac{y - \zeta}{\sigma(y)} \right) \delta_0(\zeta) + \left( 1 - \Phi \left( \frac{y - \zeta}{\sigma(y)} \right) \right) \delta_0(1 - \zeta) \]

\( \phi \) and \( \Phi \) are p.d.f. and c.d.f. of \( \mathcal{N}(0,1) \)

\( \delta_0 \) is Dirac delta function \( \chi_{[0,1]} \) is characteristic (indicator) function of interval \([0,1]\)
Expectations and variances

\[ E \{ \tilde{z} | y \} = \tilde{y} = \Phi \left( \frac{\overline{y}}{\sigma(y)} \right) y - \Phi \left( \frac{\overline{y} - 1}{\sigma(y)} \right) (y - 1) + \sigma(y) \phi \left( \frac{y - 1}{\sigma(y)} \right) - \sigma(y) \phi \left( \frac{\overline{y} - 1}{\sigma(y)} \right), \]

\[ \text{var} \{ \tilde{z} | y \} = \tilde{\sigma}^2(y) = \Phi \left( \frac{\overline{y}}{\sigma(y)} \right) (y^2 - 2\overline{y}y + \sigma^2(y)) + \]
\[ + \tilde{y}^2 - \Phi \left( \frac{\overline{y} - 1}{\sigma(y)} \right) (y^2 - 2\overline{y}y + 2\tilde{y} + \sigma^2(y) - 1) + \]
\[ + \sigma(y) \phi \left( \frac{\overline{y} - 1}{\sigma(y)} \right) (2\tilde{y} - y - 1) - \sigma(y) \phi \left( \frac{\overline{y} - 1}{\sigma(y)} \right) (2\tilde{y} - y). \]

These equations are “universal”, in the sense that they are valid for any variance function \( \sigma^2(y) \), including non-affine ones.

(F.SigPro2009)
Expectations and variances

\[ y = E\{z|y\}, \quad \sigma(y) = \text{std}\{z|y\}, \quad \bar{y} = E\{ar{z}|y\}, \quad \bar{\sigma}(\bar{y}) = \text{std}\{\bar{z}|y\}. \]

Standard-deviation function \( \sigma(y) = \sqrt{0.01y + 0.04^2} \) (solid line) and the corresponding standard-deviation curve \(\bar{\sigma}(\bar{y})\) (dashed line).

The gray segments illustrate the mapping \( \sigma(y) \mapsto \bar{\sigma}(\bar{y}) \).

The small black triangles indicate points \((\bar{y}, \bar{\sigma}(\bar{y}))\) which correspond to \( y = 0 \) and \( y = 1 \).
\[ a = 0.02^2, 0.06^2, 0.10^2 \]
\[ b = 0.04^2 \]
Model does indeed fit the data

(F. et al. TIP 2008)
Limit cases and patologies

\( \sigma(y) = \alpha y, \quad \alpha = 1, \frac{1}{2} \)

\( \sigma(y) = \sqrt{3y - 4} \)

\( \sigma(y) = \frac{1}{4} e^y \)

\( \sigma(y) = 4y^2 - 2y + \frac{1}{4} \)

(F.SigPro2009)
2. Variance Stabilization
Motivation

*Signal-dependent errors* are particularly undesirable because

- basic data analysis and processing methods (such as those studied in earlier courses),
- standard statistical procedures implemented in computing environments (Matlab, R, Mathematica, etc.),
- off-the-shelf algorithms,

are typically designed and implemented for *identically distributed errors*.

Variance stabilization attempts to make the variance of the errors to be the same.
Variance-stabilization problem

Find a function $f : Z \rightarrow \mathbb{R}$ such that the transformed variable $f(z)$ has constant standard deviation, say, equal to 1, $\text{std} \{ f(z) | \theta \} = 1$.

such $f$ is a variance-stabilizing transformation (VST)

\[ f \text{ should be independent of } \theta \]

Benefits:

- the (conditional) standard deviation does not depend anymore on the distribution parameter;
- heteroskedastic $z$ turns into a homoskedastic $f(z)$. 
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics
Variance stabilization: heuristics

Classic **heuristic** stabilizer as indefinite integral form

\[
    f(z) = \int z \frac{1}{\sigma(\theta)} d\mu(\theta).
\]

Idea: consider a local first-order expansion of \( f \) at \( \mu(\theta) \)
(i.e., assume \( \sigma(\theta) \) locally constant),

\[
    f(z) \approx f(\mu(\theta)) + (z - \mu(\theta)) \frac{\partial f}{\partial z}(\mu(\theta)),
\]

We have

\[
    \text{std} \{ f(z) | \theta \} \approx \frac{\partial f}{\partial z}(\mu(\theta)) \sigma(\theta),
\]
then impose \( \text{std} \{ f(z) | \theta \} = 1 \) and obtain the indefinite integral (5).

Known and used already in the 1930’s (e.g., Tippett 1934, Bartlett 1936), often rediscovered in signal processing (e.g., Prucnal&Saleh 1981, Arsenault&Denis 1981, Kasturi et al. 1983, Hirakawa&Parks 2006).

Very rough, but useful as a first guess: nearly all classical stabilizers can be seen as a slight modification of (5).
Exact variance stabilization is typically impossible to achieve

Positive result: multiplicative noise

\[ f(z) = \log |z| \]

Negative result: Bernoulli

Binary samples \( z \in \{0, 1\} \) of the Bernoulli distribution with parameter \( \theta = E \{ z | \theta \} \) cannot be stabilized to the same constant variance for different values of \( \theta \):

\[
E \{ g(z) | \theta \} = \theta g(1) + (1 - \theta) g(0)
\]

\[
\text{var} \{ g(z) | \theta \} = \text{var} \left\{ (g(z) - E \{ g(z) | \theta \})^2 | \theta \right\} = (g(0) - g(1))^2 \theta (1 - \theta).
\]

Exact stabilization is not possible for Poisson, Binomial, and most other families used in applications.

In practice, we deal with either approximate or asymptotic stabilization.
Classical variance stabilization for Poisson

\[ f(z) = \int \frac{z}{\sigma(\theta)} d\mu(\theta) = \int \frac{1}{\sqrt{\theta}} d\mu(\theta) = 2\sqrt{z}. \]

Bartlett 1936: \( 2\sqrt{z + \frac{1}{2}} \)

Anscombe 1948: \( 2\sqrt{z + \frac{3}{8}} \) (Anscombe attributes it to A.H.L. Johnson)

Freeman & Tukey 1950: \( \sqrt{z} + \sqrt{z + 1} \)

In the same way stabilizers were derived for the Binomial and Negative Binomial distribution families (“angular” transformations based on the arcsin and hyperbolic arcsin).
Variance stabilization for Poisson and related

Murtagh, Starck, and Bijaoui, 1995: Generalized Anscombe transformation (GAT) for Poisson-Gaussian noise.

\[ f_{\alpha,\sigma}(z) = \begin{cases} \frac{2}{\alpha} \sqrt{\alpha z + \frac{2}{3} \alpha^2 + \sigma^2}, & z \geq -\frac{3}{8} \alpha - \frac{\sigma^2}{\alpha} \\ 0, & z < -\frac{3}{8} \alpha - \frac{\sigma^2}{\alpha} \end{cases} \]

Asymptotically accurate stabilization for large \( y \): \( \text{var} \{ f_{\alpha,\sigma}(z) | y \} = 1 + O(y^{-2}) \)

Poor stabilization for small \( y \).

Zhang, Fadili, and Starck, 2008: Generalization of Anscombe for filtered (i.e. for linear combinations of) Poisson-Gaussian variates.

All these results enjoy some form of asymptotic optimality, but good stabilization for small \( \theta \) is never achieved.
Generalized Anscombe transformation

(a) GAT for $\sigma = 0.357$ ($\alpha = 1$)

(b) Stabilized standard deviation, obtained with the GAT in (a)
Variance stabilization: three milestone works

- Curtiss 1943: general asymptotic theorems are proved (and later Bar-Lev&Enis 1990: alternative formulation)
  - gave theoretical support to empirical stabilizers that were already used (and also to others yet to appear).

- Efron 1981: existence of transformations for exact variance stabilization and/or perfect normalization.
  - formalizes sufficient conditions for existence of exact stabilizers (“general transformation families” framework), and provides their analytical expressions.
  - results are nonparametric and nonasymptotic.
  - difficult to use in practice (assumes too much smoothness and invertibility of parametrized mappings).

- Tibshirani 1986: AVAS procedure for regression
  - approximate variance stabilizing transformations are iteratively computed by recursive application of the integral stabilizer (iterative refinement of the stabilizer)
  - developed for data-driven application, hints about potential use for random variables.
  - nonparametric and nonasymptotic.
Exact stabilization for general transformation families (Efron 1981)

Exact stabilization is possible at least for some special classes of distribution families.

**General scaled transformation family:**

\[ z = g^{-1} (p(\theta) + q(\theta) w), \]

where \( w \sim \mathcal{N}(0, 1) \) and \( g, p \) and \( q \) are smooth functions.

**General transformation family** has \( q(\theta) = q \).

Let \( z \) follow a general transformation family, \( \text{pdf}[z|\theta] \) be the conditional p.d.f. of \( z \), and \( \vartheta(\theta) = \text{med}[z|\theta] \) be the conditional median of \( z \) given \( \theta \). The exact VST \( f \) can be computed as:

\[ f(z) = \int_{-\infty}^{z} \frac{\text{pdf}[z|\theta](\vartheta)}{\phi(0)} d\vartheta \quad \text{(integration w.r.t. median)}, \]

where \( \phi \) is the p.d.f. of the standard normal \( \mathcal{N}(0, 1) \).
Optimization of VSTs: Motivation

- It is typically impossible to achieve simultaneously good stabilization for all parameter values (see Freeman & Tukey): thus, when a stabilizer appears to be better than another for some values of the parameter, it is likely that for other values it is actually worse. In this sense, there might be no “best stabilizer”.

- There is no universal objective criterion for assessing the goodness of a stabilizer. Simply demanding $\text{std} \{ f(z) | \theta \}$ to be as close as possible to 1 is vague and ambiguous.

- Common stabilizing transformations are often based on coarse asymptotics, developed between the 1930’s and 1950’s without leveraging any numerical optimization.

(F.2009)
Variance stabilization as a minimization problem

Let

\[ e_f(\theta) = \sigma_f(\theta) - c \]

be the local error because of inexact stabilization (where locality is intended by the conditioning on \( \theta \)) and define a global cost functional as

\[ F(f) = \int |e_f(\theta)| d\theta. \]  

(6)

We may formulate the variance stabilization problem as the solution of

\[ \arg\min_f F(f) \]  

(7)

Variance stabilization is exact only when \( F(f) = 0 \) for some \( f \).

Minimization needs to be constrained to some particular class of functions, such as strictly monotone, Lipschitz, smooth functions, etc.
Variance stabilization as a minimization problem

We have seen that it makes little sense to aim at exact variance stabilization simultaneously for all parameter values.

We consider a separable weighted cost functional (stabilization functional) of the form

\[ F(f) = \int_{\Theta} w_\theta (\theta) w_e (e_f (\theta)) d\theta, \]

where the weight functions \( w_\theta \) and \( w_e \) provide different weighting for the different values of \( \theta \) and different stabilization errors \( e_f (\theta) \), respectively.

In particular, we design special weights \( w_e \) that favor approximate stabilization while ignoring very large stabilization errors.
Stabilization functional

Let $\gamma_0, \gamma_1 \leq 1$, $r_0', r_1' \geq 0$, $r_0'' \geq r_0'$, $r_1'' \geq r_1'$, $o_0, o_1 \geq 1$ be some real constants and $\chi$ be the characteristic (indicator) function of a set $\cdot$.

We define the weights $w_e$ as

$$w_e(ef(\theta)) = |\varphi(\sigma_T(\theta))\sigma_f(\theta)|,$$

where

$$\sigma_f(\theta) = \sigma_T(\theta) - c = \max \{-r''_0, \min \{r''_0, ef(\theta)\}\},$$

$$\sigma_f(\theta) = \max \{c - r''_0, \min \{c + r''_0, \sigma_f(\theta)\}\},$$

and with the function $\varphi$ given by

$$\varphi(ef) = \gamma_0 \cdot \chi_{[0, +\infty)}(ef) \left\{1 - \left(\frac{ef - r''_0}{r''_0}\right)^2\right\}^{(o_0 - 1)} \chi_{(-\infty, r''_0)}(ef) + \chi_{[r''_0, +\infty)}(ef) +$$

$$+ \gamma_1 \cdot \chi_{(-\infty, 0)}(ef) \left\{1 - \left(\frac{ef + r''_1}{r''_1}\right)^2\right\}^{(o_1 - 1)} \chi_{(-r''_1, +\infty)}(ef) + \chi_{(-\infty, -r''_1]}(ef) \right\}. $$
Stabilization functional

The clipped argument $\overline{\varphi} (\theta)$ cannot distinguish stabilization errors larger than $r_1^\prime, r_0^\prime$, while the multiplication against the function $\varphi$ increases the order of the stabilization errors from 1 to $o_1, o_0$. Note that for a positive (resp. negative) argument, the function $\varphi$ has a zero of order $o_u - 1 (o_l - 1)$ at zero and becomes constant (with quadratic-smooth joint) equal to $\gamma_u (\gamma_l)$ starting from $r_u^\prime (r_l^\prime)$.

Thus, the cost functional $F(f)$ takes the form

$$F(f) = \int_{\Theta} w_\theta (\theta) |\varphi (\overline{\varphi} (\theta)) \overline{\varphi} (\theta)| d\theta.$$
Iterative integral algorithm for optimizing $f$

0. **Initialize**

$f_0(z) = z$ (identity) or an arbitrary (non-optimal) stabilizer

Iterate the following three stages:

1. **Compute statistics**

   \[
   \vartheta_k(\theta) = \text{med} \{ f_k(z) \mid \theta \} = f_k(\text{med} \{ z \mid \theta \})
   \]

   \[
   \sigma_k(\theta) = \text{std} \{ f_k(z) \mid \theta \}
   \]

2. **Compute stabilization refinement**

   \[
   r_k(z) = \int^z I_k(\theta) d[\vartheta_k(\theta)]
   \]

   (integration with respect to the median)

   where

   \[
   I_k(\theta) = 1 - \frac{w_0(\theta) \varphi(\sigma_k(\theta)) \sigma_k(\theta)}{\sigma_k(\theta)}
   \]

   \[
   \sigma_k(\theta) = \sigma_k(\theta) - c = \max \{-r_k''(r_k''', \min \{ r_k''', c_k(\theta) \} \}
   \]

   \[
   \sigma_k(\theta) = \max \{ c - r_k''(c + r_k''', \sigma_k(\theta)) \}
   \]

3. **Compose**

   \[
   f_{k+1}(z) = r_k(f_k(z))
   \]
Optimization of Poisson stabilizer (iterative integral)
Optimization of Poisson stabilizer (iterative integral)\textsuperscript{80}

\[
\alpha_1, \alpha_2 = 1.5, \quad \beta_1, \beta_2 = 0.2, \quad \gamma_1, \gamma_2 = 0.5, \quad \gamma_3, \gamma_4 = 0.8
\]

stabilization functional \( F(f_k) \) vs. iterations (log scale)

Optimization of Poisson stabilizer (iterative integral)

\[ \frac{\alpha_0, \beta_0}{\rho, \rho'} = 1.5, \quad \lambda_0, \lambda' = 0.2, \quad \lambda_0', \lambda'' = 0.5, \quad \gamma, \gamma_1 = 0.8 \]

Variance-stabilizer \( f \) and the mapping \( E \{ z \mid \theta \} \rightarrow E \{ f(z) \mid \theta \} \)

Stabilization functional \( F(f) = 0.1051 \)
Optimization by iterative integral vs. direct search

Convergence of the iterative integral algorithm, with monotonically decreasing cost, was verified experimentally, up to the numerical precision of the algorithm, in extensive tests. However, its limit may differ from the minimizer of the stabilization functional.

Further drawbacks:
— computational aspects involved in the evaluation of the integrals
— a proof of minimization seems very difficult to achieve (similar situation as for AVAS algorithm)

A practical way to circumvent these issues is to solve the minimization by direct search, which is particularly feasible for discrete distributions.

We use Nelder-Mead downhill simplex algorithm.
Optimization by direct search

\[ \alpha_1, \theta_1 = 1.5, \, \gamma_1, \gamma_1' = 0.2, \, \gamma_1'', \gamma_1''' = 0.5, \, \gamma_1', \gamma_1 = 0.8 \]

variance-stabilizer \( f \) and the mapping \( E\{z|\theta\} \mapsto E\{f(z)|\theta\} \)

stabilization functional \( F(f) = 0.096 \)
Optimization by direct search: relaxing monotonicity

\[ \alpha, \beta = 1.5, \gamma', \gamma'' = 0.2, \gamma''', \gamma'''' = 0.5, \gamma, \gamma_1 = 0.8 \]

variance-stabilizer \( f \) and the mapping \( E \{ z | \theta \} \rightarrow E \{ f (z) | \theta \} \)

stabilization functional \( F (f) = 0.079 \)
Optimization by direct search

\[ \alpha, \beta = 1.5, \gamma, \gamma' = 0.2, \gamma'', \gamma''' = 0.5, \gamma, \gamma' = 0.8 \]
Optimization by direct search

\[ \alpha, \beta = 1.5, \gamma, \gamma' = 0.2, \gamma'', \gamma''' = 0.5, \gamma, \gamma' = 0.8 \]
Regularization of VSTs through penalization of the stabilization functional

Introduce penalty terms into the stabilization functional $F(f)$:

$$F(f) = F_{\text{stabil}}(f) + \lambda_{\text{smooth}} \cdot F_{\text{smooth}}(f) + \lambda_{\text{asympt}} \cdot F_{\text{asympt}}(f) + \lambda_{\text{inverse}} \cdot F_{\text{inverse}}(f),$$

where $\lambda_{\text{smooth}}, \lambda_{\text{inverse}}, \lambda_{\text{asympt}} \geq 0$ are penalty parameters.

Constrain direct-search optimization to VSTs $f$ for which the expectations mapping

$$E\{z|\theta\} \mapsto E\{f(z)|\theta\}$$

is strictly increasing, so to be able to define the exact unbiased inverse $I_f$

$$I_f : E\{f(z)|\theta\} \mapsto E\{z|\theta\}.\quad \text{(F.ISBI2011)}$$

| Accuracy of stabilization | $F_{\text{stabil}}(f) = \int_{\theta_{\text{min}}}^{\theta_{\text{max}}} (\text{std} \{ f(z)|\theta \} - 1)^2 \, d\theta$ |
| Smoothness of $f$          | $F_{\text{smooth}}(f) = \int_{z_{\text{min}}}^{z_{\text{max}}} (f''(z))^2 \, dz$ |
| Asymptotic                | $F_{\text{asympt}}(f) = \int_{z_{\text{min}}}^{z_{\text{max}}} \left( z - f_{\text{asympt}}(z) \right)^2 \, dz$ |
|                          | ... other penalties, e.g. higher-order moments of the distribution of $f(z)$ |
Regularized VSTs for the Rician family of distributions

\[ f(z) \], \[ \text{std} \{ f(z) | \theta \} \]

\( \lambda_{\text{asympt}} = 1, \lambda_{\text{smooth}} = 10^{-2}, \lambda_{\text{inverse}} = 10^{-4}. \)
Regularized VSTs for the Rician family of distributions

\[ f(z) = \lambda_{\text{asympt}} = 1, \lambda_{\text{smooth}} = 10^{-4}, \lambda_{\text{inverse}} = 0. \]

(F.ISBI2011)
Regularized VSTs for the Rician family of distribution

\[
\lambda_{\text{asympt}} = 1, \quad \lambda_{\text{smooth}} = 10^{-6}, \quad \lambda_{\text{inverse}} = 10^{-\frac{5}{2}}.
\]

(F. ISBI 2011)
Regularized VSTs for the Rician family of distributions

\[ f(z) \quad \text{std}\{f(z) | \theta\} \]

\[ \lambda_{\text{asympt}} = 1, \lambda_{\text{smooth}} = 10^{-8}, \lambda_{\text{inverse}} = 0. \]

(F.ISBI2011)
Optimization of rational polynomial VST

To effectively regularize the optimization, we can also seek the solution within a specific class of functions.

**Poisson-Gaussian VST optimization**

Find stabilizer by optimizing the coefficients of polynomials $P(z)$ and $Q(z)$ in

$$f_{1,\sigma}(z) = 2 \sqrt[2]{\frac{\sum_{i=0}^{N} p_i z^i}{\sum_{i=0}^{M} q_i z^i}} = 2 \sqrt[2]{\frac{P(z)}{Q(z)}}.$$  \hspace{1cm} (9)

Constrain polynomials such that the VST necessarily approaches the GAT asymptotically. In this way, the optimized VST always attains good asymptotic stabilization:

$$\frac{P(z)}{Q(z)} - z - \frac{3}{8} - \sigma^2 \to 0 \text{ as } z \to +\infty$$  \hspace{1cm} (10)

at a rate of $O(z^{-1})$. For $N = 3$ we have

$$f_{1,\sigma}(z) = 2 \sqrt[2]{\frac{p_3 z^3 + p_2 z^2 + p_1 z + p_0}{p_3 z^2 + [p_2 - p_3 (3/8 + \sigma^2)] z + 1}}$$  \hspace{1cm} (11)

which depends solely on $\{p_i\}_{i=0}^{3}$.

(MF.TIP2014)

3. Noise parameter estimation
3.1. Scatterplot methods for signal-dependent noise estimation

Goal: estimate the standard-deviation function.

Approach: build a scatterplot (mean, st.dev), fit a curve.

Employ some local or nonlocal low-pass (for mean) and high-pass filtering (for st.dev.);
e.g., split image into wavelet approximation and detail coefficients.

Challenge: ignore edges or high-frequency texture

1. Partitioning of the codomain to pair mean and st.dev. estimates (conditioning)
2. Use wavelet approximation coefficients to estimate conditional expectations
3. Use wavelet detail coefficients to estimate conditional standard-deviation (use MAD)
4. Fit parametric model using nonlinear optimization to maximize posterior likelihood
   (or any other fitting criterion).

Importance of a good parametric model

complex targets with incomplete/sparse codomain
Importance of a good parametric model
3.2. Signal-dependent noise estimation using VST

Goal: estimate the standard-deviation function.

Idea: Different standard-deviation functions are typically stabilized by different VSTs: finding a VST that stabilizes the data can be equivalent to finding the standard-deviation function.

Challenges:
- stabilization is typically inaccurate even when the standard-deviation function is known;
- detecting noise-parameter mismatch

The generic algorithm iterates the following steps:

1. Apply VST $f_\sigma$ based on current estimate $\hat{\sigma}$ of st.dev. function $\sigma$.

2. Assess stabilization of $f_\sigma (z)$:
   - If unable to improve stabilization further, the current $\hat{\sigma}$ is the final estimate;
   - else, modify $\hat{\sigma}$ and go to 1.
Standard deviation of the transformed data $\text{std}\{f_{\lambda}(z) | \nu, 1\}$, for different values of $\lambda$, as indicated by the italic numbers superimposed on the curves. Stabilizer $f$ on page 98.

The stabilizer $f_\lambda$ is asymptotically affine for large $z$, with derivative approaching $\frac{1}{\lambda}$. Thus,

$$\text{std}\{f_{\lambda\sigma}(z) | \sigma \nu, \sigma\} = \text{std}\{f_{\lambda}(z) | \nu, 1\} \xrightarrow[\nu \to +\infty]{\nu} \frac{1}{\lambda}$$

(12)

In other words, for large $\nu$, the stabilized standard deviation is approximately equal to the reciprocal of the under- or over-estimation factor.
Rice: Noise-level estimation

General iterative scheme based on variance stabilization aimed at estimating the value of the \( \sigma \) parameter from a single realization \( z \).

Let \( E \) denote an estimator of the standard deviation \( \sigma \) of the homoskedastic noise corrupting a signal. Popular examples for estimating \( \sigma \) of AWGN in natural images are the median or mean absolute deviation of the high-pass filtered signal:

\[
\begin{align*}
\mathcal{E}_{\text{MedianAD}} \{ z \} &= \text{med} \{ |H \{ z \}| \}/\Phi^{-1}(3/4), \\
\mathcal{E}_{\text{MeanAD}} \{ z \} &= \text{mean} \{ |H \{ z \}| \} \sqrt{\pi/2},
\end{align*}
\]

where \( H \{ z \} = z \ast w_{hi} \), and \( w_{hi} \) is a high-pass convolutional kernel having zero mean and unit \( L^2 \)-norm,

\[
\int w_{hi} = 0, \quad \int |w_{hi}|^2 = 1,
\]

such as, e.g., a wavelet function.

(F.ISBI2011)
The proposed scheme is expressed by the following recursive system:

\[
\begin{cases}
\hat{\sigma}_0 = \mathcal{E}\{z\}, \\
\hat{\sigma}_{k+1} = \mathcal{E}\{f_{\hat{\sigma}_k}(z)\} \hat{\sigma}_k, \quad k \geq 0.
\end{cases}
\] (13)

The idea of this recursion originates from (12). The estimate \(\hat{\sigma}_k\) is used to define a variance-stabilizing transformation for \(z\). If the estimated value \(\hat{\sigma}_k\) is correct, then the transformation \(f_{\hat{\sigma}_k}\) successfully stabilizes the data and when \(\mathcal{E}\) is applied to the stabilized data it should return a value \(\mathcal{E}\{f_{\hat{\sigma}_k}(z)\}\) close to 1. If the estimated value \(\hat{\sigma}_k\) is not correct (e.g., an under-estimate of \(\sigma\)), then the stabilization is not accurate, being roughly the inverse of the mis-estimation ratio, \(\mathcal{E}\{f_{\hat{\sigma}_k}(z)\} \approx \frac{\hat{\sigma}}{\sigma}\). Hence, we correct the current estimate \(\hat{\sigma}_k\) by multiplying it with \(\mathcal{E}\{f_{\hat{\sigma}_k}(z)\}\). Observe that if \(\mathcal{E}\{f_{\hat{\sigma}}(z)\} = 1\) for some value \(\hat{\sigma}\), then this \(\hat{\sigma}\) is a fixed point for (13) and we want the sequence \(\hat{\sigma}_k\) to converge to such \(\hat{\sigma}\). The system (13) is initialized by the estimator \(\mathcal{E}\) applied on the non-stabilized data \(z\).

Under very general conditions, the iterative scheme (13) is guaranteed to converge with exponential rate to an accurate and stable estimate \(\hat{\sigma}\) of the true value \(\sigma\).
Standard deviation contours in Poisson-Gaussian noise

Let $z_{\alpha,\sigma}$ be a Poisson-Gaussian image with (true) parameters $\alpha, \sigma$.

Let $B$ be an image block, with $p_B(y)$ being the probability density of $y$ over this block.

Let $\hat{\alpha}, \hat{\sigma}$ be (possibly erroneous) estimates of $\alpha, \sigma$.

Consider the VST $f_{\hat{\alpha}, \hat{\sigma}}$ (such as GAT or an optimized VST).

Denote the average standard deviation of $f_{\hat{\alpha}, \hat{\sigma}}(z_{\alpha,\sigma})$ over $B$ as

$$F_B(\hat{\alpha}, \hat{\sigma}) := \mathbb{E}_B \{f_{\hat{\alpha}, \hat{\sigma}}(z_{\alpha,\sigma})\} = \int \text{std} \{f_{\hat{\alpha}, \hat{\sigma}}(z_{\alpha,\sigma}) | y\} p_B(y) dy.$$  

$F_B(\hat{\alpha}, \hat{\sigma})$ is a bivariate function of the parameter estimates $\hat{\alpha}, \hat{\sigma}$.

Under some simplifying assumptions, the unitary standard-deviation contours $F_B(\hat{\alpha}, \hat{\sigma}) = 1$ are smooth curves in a neighbourhood of the true parameter values $(\alpha, \sigma)$.

We apply the results by devising a VST-based algorithm for estimating $\alpha$ and $\sigma$.

(M.&F.TIP2014)
$(\hat{\alpha}, \hat{\sigma})$ plane and the true parameters $(\alpha, \sigma)$

(M.&F.TIP2014)
\((\hat{\alpha}, \hat{\sigma})\) plane and \(F_B(\hat{\alpha}, \hat{\sigma}) - 1\)
Unitary contour of $F_B(\hat{\alpha}, \hat{\sigma})$
$F_B(\hat{\alpha}, \hat{\sigma}) - 1$ for different blocks $B$
$F_B (\hat{\alpha}, \hat{\sigma}) - 1$ for different blocks $B$
Intersecting contours $F_B (\hat{\alpha}, \hat{\sigma}) = 1$
Standard deviation contours: Example (GAT)

(a) peak 120, $\alpha = 1$, $\sigma = 5$

(b) GAT contours

Ten standard deviation contours $F_B (\hat{\alpha}, \hat{\sigma}) = 1$ computed from ten randomly selected $32 \times 32$ blocks $B$ of the $512 \times 512$ image (a).
Standard deviation contours: Propositions

- We assume two ideal hypotheses:
  1. We can achieve exact stabilization with the correct noise parameters $\theta$:
     \[ \text{std} \{ f_{a,\sigma} (z_{a,\sigma}) | y \} = 1 \forall y \geq 0. \] (14)

  2. For any VST $f_{\tilde{\alpha},\tilde{\sigma}}$ and any choice of parameters $(\tilde{\alpha}, \tilde{\sigma})$ and $\alpha, \sigma$, the approximation
     \[ \text{std} \{ f_{\tilde{\alpha},\tilde{\sigma}} (z_{a,\sigma}) | y \} \approx \text{std} \{ z_{a,\sigma} | y \} f'_{\tilde{\alpha},\tilde{\sigma}} (E \{ z_{a,\sigma} | y \}) \] (15)
     holds exactly.

**Proposition 1.** The mean standard deviation of the stabilized image block $f_{\hat{\alpha},\hat{\sigma}} (z_{a,\sigma})$ can now be written as
\[ E_B \{ f_{\hat{\alpha},\hat{\sigma}} (z_{a,\sigma}) \} = \int \frac{\text{std} \{ z_{a,\sigma} | y \}}{\text{std} \{ z_{\hat{\alpha},\hat{\sigma}} | y \}} p_B (y) dy. \] (16)

**Proposition 2.** Given the assumptions in Proposition 1, $F_B (\hat{\alpha}, \hat{\sigma})$ has a well-behaving (locally smooth and simple) unitary contour near the true parameter values $\alpha, \sigma$.

\[ \text{M.\&F.TIP2014} \]
Standard deviation contours: Example (GAT)

(a) peak 120, $\alpha = 1, \sigma = 5$

(b) GAT contours

Ten standard deviation contours $F_B (\hat{\alpha}, \hat{\sigma}) = 1$ computed from ten randomly selected $32 \times 32$ blocks $B$ of the $512 \times 512$ image (a).
Standard deviation contours: Example (GAT)

(a) peak 120, $\alpha = 1$, $\sigma = 5$

(b) GAT contours

Ten standard deviation contours $F_B (\hat{\alpha}, \hat{\sigma}) = 1$ computed from ten randomly selected $32 \times 32$ blocks $B$ of the $1193 \times 795$ image (a).
Standard deviation contours: Example (Opt.VST)

(a) peak 120, $\alpha = 1, \sigma = 5$

(b) GAT contours

Ten standard deviation contours $F_B (\hat{\alpha}, \hat{\sigma}) = 1$ computed from ten randomly selected $32 \times 32$ blocks $B$ of the $1193 \times 795$ image (a).
Application to parameter estimation

- The contours \( F_B(\bar{a}, \bar{\sigma}) = 1 \) corresponding to different stabilized blocks \( B \) are locally smooth in the \((\bar{a}, \bar{\sigma})\) plane.

- Typically different blocks yield differently oriented curves intersecting each other.

- The intersection has coordinates \((\alpha, \sigma)\), i.e. the true parameters.

- A cost functional measuring the lack of stabilization is minimized at the intersection.

(M.&F.TIP2014)
Parameter estimation algorithm

1. Initialize the estimates $\hat{\alpha}$ and $\hat{\sigma}$.
2. Choose $M$ random blocks $B_m$, $m = 1, \ldots, M$ from the noisy image $z_{\alpha, \sigma}$.
3. Apply a VST $f_{\hat{\alpha}, \hat{\sigma}}(z_{\alpha, \sigma})$ to each block.
4. Compute an estimate $F_{B_m}(\hat{\alpha}, \hat{\sigma}) = E_{B_m}\{f_{\hat{\alpha}, \hat{\sigma}}(z_{\alpha, \sigma})\}$ for the standard deviation of each stabilized block, using any AWGN standard deviation estimator $E$.
5. Optimize $\hat{\alpha}$ and $\hat{\sigma}$ so to minimize the difference between $F_{B_m}(\hat{\alpha}, \hat{\sigma})^2$ and 1 (target variance) over the $M$ blocks.

- We implement the proposed approach in Matlab, using the optimized VSTs (or GAT for comparison), and minimizing the cost functional
  \[ C(\hat{\alpha}, \hat{\sigma}) = \text{mean}_{m=1,\ldots,M} \left| F_{B_m}(\hat{\alpha}, \hat{\sigma})^2 - 1 \right|. \]
- $E$ is sample standard deviation of wavelet detail coefficients.
- We estimate $F_{B_m}(\hat{\alpha}, \hat{\sigma})$ from $M = 2000$ randomly selected $32 \times 32$ image blocks.

- Combined with the optimized VSTs, the algorithm yields results that are competitive with the results obtained with scatterplot method (Foi et al., 2008).
- The optimized VSTs play an important role in the estimation performance for the low-intensity cases.
  - The GAT is inherently unable to accurately stabilize regions with low mean intensity; this violates our assumption that \(\text{std} \{ f_\theta (z_\theta) \mid y \} = 1 \text{ for } y \geq 0\).
  - Optimized VSTs provide highly accurate stabilization also for low intensities.
4. Exact unbiased inversion of VST in denoising
Three steps: stabilization, denoising, and inversion

VSTs are often exploited for the removal of signal-dependent noise through the following three-step procedure:

1. Noise variance is stabilized by applying a VST $f$ to the data; this produces a signal in which the noise can be treated as additive with unitary variance.

2. Noise is removed using a conventional denoising algorithm – denoted by $\Phi$ – for additive homoskedastic noise (e.g., additive white Gaussian noise).

3. An inverse transformation is applied to the denoised signal, obtaining the estimate of the signal of interest.

Denoising algorithms attempt to estimate the expectation, thus, $D = \Phi(f(z))$ can be treated as an approximation of $E[f(z)|\theta]$. 
Since $f$ is necessarily a nonlinear mapping, we may have
\[ E(f(z)|\theta) \neq f(E(z|\theta)), \]
and, thus,
\[ f^{-1}(E(f(z)|\theta)) \neq E(z|\theta), \]
which means that the inverse transformation applied after denoising (Step 3.) should not coincide with the algebraic inverse of $f$, as this would introduce bias in the estimation of $E\{z|\theta\}$ from the observed $z$.

The problem of bias in variance-stabilized denoising is solved by the exact unbiased inverse that is defined by the mapping
\[ I_f : E\{f(z)|\theta\} \rightarrow E\{z|\theta\} = \mu. \]
This definition assumes that the mapping $E\{z|\theta\} \rightarrow E\{f(z)|\theta\}$ is invertible. In particular, we require this mapping to be strictly increasing, or, equivalently, that $E\{f(z)|\theta\}$ is strictly increasing with $\theta$. This condition supplants the traditional requirement of invertibility of $f$, which instead we may allow to be nonmonotone.

Under modest hypotheses, it can be shown that $I_f(D)$ is a maximum-likelihood estimate of $\theta$. 
Inversion for Poisson stabilized by Anscombe

Let $z$ be Poisson distributed data.

Applying the Anscombe transform yields $f(z) = 2\sqrt{z + \frac{3}{8}}$.

After filtering of $f(z)$ we obtain $D = \Phi(f(z))$, which we treat as an approximation of $E\{f(z)\mid \theta\}$.

**Algebraic inverse:**

$$I_A(D) = f^{-1}(D) = \left(\frac{D}{2}\right)^2 - \frac{3}{8}$$

**Asymptotically unbiased inverse:**

$$I_B(D) = \left(\frac{D}{2}\right)^2 - \frac{1}{8}.$$ Typically used in applications.

**Exact unbiased inverse:**

$$I_C : E\{f(z) \mid y\} \mapsto E\{z \mid y\}.$$ We have discrete Poisson probabilities $P(z \mid y)$, so

$$E\{f(z) \mid y\} = \sum_{z=0}^{+\infty} f(z) P(z \mid y) = 2 \sum_{z=0}^{+\infty} \left(\sqrt{z + \frac{3}{8}} \cdot \frac{y^z e^{-y}}{z!}\right).$$

The definition of $I_C$ is implicit, but we can have a closed form approximation as

$$I_C(D) \approx \frac{1}{4} D^2 + \frac{1}{4} \sqrt{\frac{3}{2}} D^{-1} - \frac{11}{8} D^{-2} + \frac{5}{8} \sqrt{\frac{3}{2}} D^{-3} - \frac{1}{8}.$$

(M.&F.TIP2011)
Exact unbiased inverse of Generalized Anscombe Transform for Poisson-Gaussian noise

(M.&F.TIP2013)

Without loss of generality, we can fix $\alpha = 1$ and use scaling for $\alpha \neq 1$.

The EUI of GAT is constructed analogous to the EUI of the Anscombe transformation:

$$I_\alpha : E \{ f_\sigma (z) \mid y, \sigma \} \longmapsto E \{ z \mid y, \sigma \} .$$

$$E \{ f_\sigma (z) \mid y, \sigma \} = \int_{-\infty}^{+\infty} f_\sigma (z) p(z \mid y, \sigma) \, dz =$$

$$= \int_{-\infty}^{+\infty} 2\sqrt{z + \frac{3}{8} + \sigma^2} \sum_{k=0}^{+\infty} \left( \frac{y^k e^{-y}}{k! \sqrt{2\pi\sigma^2}} e^{-\frac{(z-k)^2}{2\sigma^2}} \right) \, dz .$$

Closed form approximation:

$$I_\sigma (D) \cong \frac{1}{4} D^2 + \frac{1}{4} \sqrt{\frac{3}{2}} D^{-1} - \frac{11}{8} D^{-2} + \frac{5}{8} \sqrt{\frac{3}{2}} D^{-3} - \frac{1}{8} - \sigma^2 .$$

Denoising doubly censored noisy images

Denoising heteroskedastic data using variance-stabilization and conventional denoising algorithm for AWGN.

Main stages:
1. variance-stabilization
2. denoising (BM3D public code for AWGN from www.cs.tut.fi/~foi/GCF-BM3D/ )
3. inversion of the stabilizer, including EUI and declipping (from $E \{ f (\tilde{z}) \mid y \rightarrow y \}$

We compare two alternatives stabilizers:

$$f_0(t) = \int_{t_0}^{t} \frac{c}{\tilde{\sigma}(y)} dy, \quad t, t_0 \in [0, 1]$$
